many astronomical sources vary - describe, classify and select astronomical sources by their variability

Discovery of Variable Stars

historically: discovered sporadically

periodic variable stars:

1596: David Fabricius noted that the star α Ceti (now known as Mira) was sometimes visible, sometimes not

1638: Johannes Holwarda found a visibility cycle of 11 months for Mira

1700s: William Herschel discovered the variability of α Herculis and 44 Bootis

Discovery of Variable Stars

1638: Johannes Holwarda found a visibility cycle of 11 months for Mira

1700s: William Herschel discovered the variability of α Herculis and 44 Bootis

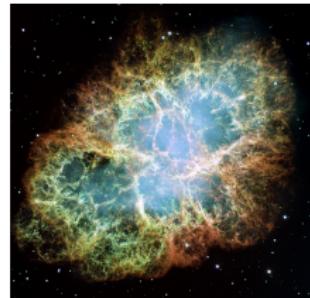

supernovae:

oldest mention of a “new star”: 185 AD a “guest star” was observed by Chinese astronomers

1054: supernova mentioned by Chinese astronomers

1572: Tycho's supernova

1604: Johannes Kepler's supernova

The Crab Nebula is a pulsar wind nebula associated with the 1054 supernova.

1911: founding of the American Association of Variable Star Observers (AAVSO)

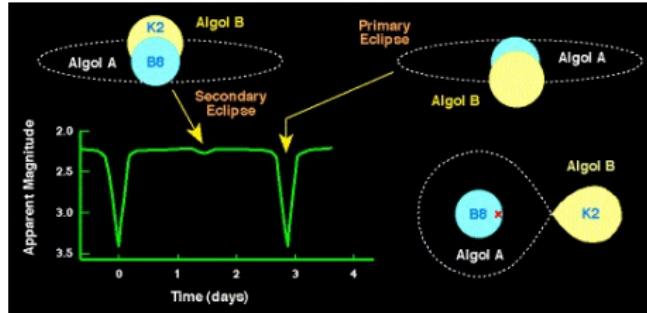

Discovery of Variable Stars

causes of variability?

John Goodricke and Edward Pigott: proposed the theory that Algol's variability might be caused by eclipses of the star by a planetary companion

we know today:

Algol is a three-star system, consisting of β Persei (Per) A, β Per B and β Per C. They regularly pass in front of each other, causing eclipses. This is an **eclipsing binary star**.

(Early) Classification of Variable Stars

systematic observation of variable stars revealed **differences in their light curves**

Pigott (1780s): variable stars: nova, long-period variables, short-period variables

Pigott (1780s): variable stars: nova, long-period variables, short-period variables

Pickering (1880s): a more detailed scheme:

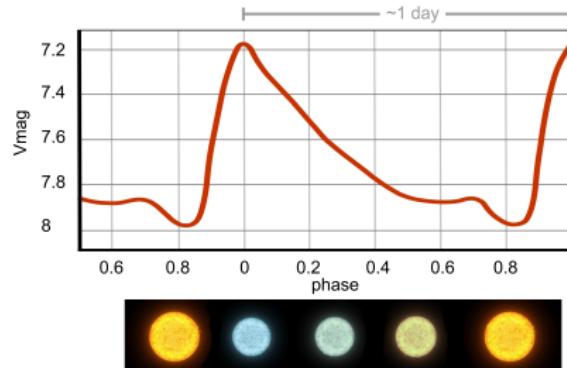

- (Ia) normal novae: now known to be nearby ones in our own galaxy;
- (Ib) novae in nebulae: now known to be supernovae in other galaxies;
- (IIa) long-period variables: cool, large-amplitude pulsating variables;
- (IIb) U Geminorum stars: dwarf novae;
- (IIc) R Coronae Borealis stars: stars which suddenly and unpredictably decline in brightness;
- (III) irregular variables: a motley collection;
- (IVa) short-period variables such as Cepheids and RR Lyrae stars;
- (IVb) Beta Lyrae type eclipsing variables; and
- (V) Algol type eclipsing variables.

Pulsating Variable Stars

underlying physics of variability:

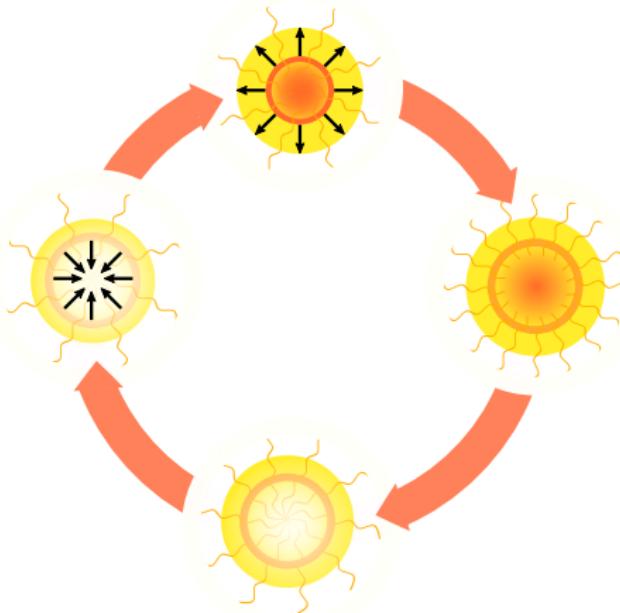

idea: (at least some) periodic variability might be caused by pulsations (A. Ritter 1873)

Observational studies by Harlow Shapley and others around 1915, and the concurrent theoretical studies by Eddington, established the pulsational nature of the Cepheids, cluster type variables (RR Lyrae stars), and long-period variables.

Cause of Pulsation

cause of pulsation: Lack of hydrostatic equilibrium beneath the surface drives the pulsation cycle with expansion and contraction of the outer layers of a star and subsequent change in brightness:

Further Pulsation Analysis

This is called **radial mode** pulsation. It is found in large-amplitude pulsating variables in the HR-diagram *instability strip*: Cepheids, Miras and RR Lyrae stars.

There are stars whose pulsation is **non-radial**: a star changes shape, but not volume. Non-radial pulsation leads to smaller amplitudes of variation. Some stars – β Cephei, δ Scuti stars and to a small amount also RR Lyrae stars – pulsate in both radial and non-radial modes.

models of stars with non-radial pulsations (copyright Coen Schrijvers)

Cepheids

- brightness enables us to observe them in other galaxies in our Local Group (such as the Magellanic Clouds, M31 and M33)
- period-luminosity relation makes them important standard candles \Rightarrow distance ladder

RR Lyrae stars

- numerous in the Milky Way halo (globular clusters), thus once called *cluster variables*
- less bright than Cepheids
- period-luminosity relation and their age makes them important tracers of the old Milky Way halo substructure

Cepheids

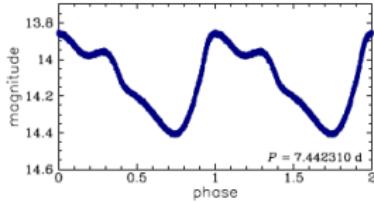

Motivation
Variable Stars
Pulsating Variable Stars
Distances
Further Pulsation Analysis

Classical (Type I) Cepheids

bright yellow, highly luminous,
supergiant pulsating variables

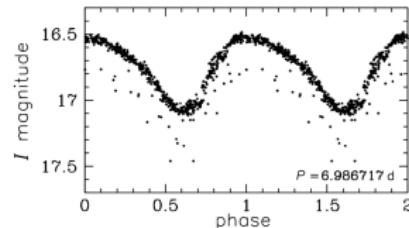

- amplitudes: $\sim 0.01 - 2 \text{ mag}_V$
- periods: 1 - 135 days
- variability is strictly regular
- spectral type: F at maximum light, G to K at minimum light;
the longer the period, the later the spectral type

Population II (Type II) Cepheids

similar light curve than Type I, but different evolutionary history

- older, low mass stars
- important fossils of the first generation of stars in our galaxy

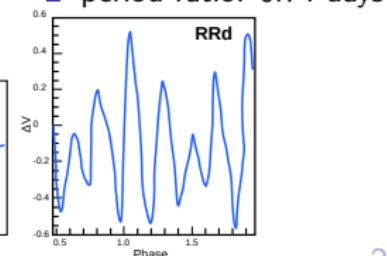

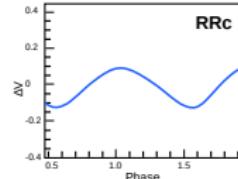

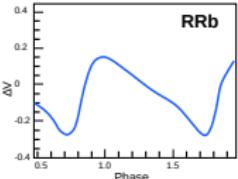

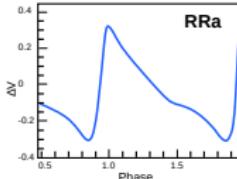

RR Lyrae stars

prototype: RR Lyrae (variability discovered by Williamina Fleming, ~ 1900); RR Lyrae stars are old helium-burning variable stars of spectral type A5 to F5 with $0.5 M_{\odot}$

Motivation
Variable Stars
Pulsating Variable Stars
Distances
Further Pulsation Analysis

- RRab**
asymmetrical light curves with steep ascend
 - periods: 0.3 - 1.2 days
 - amplitudes: 0.5 - 2 mag_V
- RRc**
nearly symmetrical light curves
 - periods: 0.2 - 0.5 days
 - amplitudes: < 0.8 mag_V
- RRd**
double-mode RR Lyrae stars, fundamental and first overtone
 - fundamental period: 0.5 days
 - period ratio: 0.74 days

RR Lyrae stars

period-amplitude-shape modulation is today known as the **Blazhko effect**

its explanation remains one of the enduring mysteries in astrophysics to this day

two promising **theories** for explaining the Blazhko effect:

- (i) resonance between the radial fundamental period of pulsation, and a non-radial period; or
- (ii) a deformation or splitting of the radial period by a magnetic field in the star

Evolutionary Stages - the Hertzsprung-Russel (H-R) Diagram

early 20th century: E. Hertzsprung and H. N. Russell noted that a scatter plot of a measure of stellar **luminosity** (absolute magnitude) vs. a measure of the stellar **temperature** (spectral type, color) shows structure:

giants: After $\sim 10\%$ of the mass of a $M < M_{\odot}$ star has been converted from H to He, the star expands: it becomes a red giant with a helium core and a hydrogen burning shell. The star heats up and moves along the horizontal branch in the H-R diagram, then cools off as the core burning stops. The once again red star then goes to higher luminosity on the asymptotic giant branch (AGB). Finally it ejects its envelope and becomes a planetary nebulae containing a white dwarf ($M \leq 1.4M_{\odot}$, $R \sim R_{\text{earth}}$).

The Period-Luminosity(-Metallicity) Relation

Motivation
Variable Stars
Pulsating Variable Stars
Distances
Further Pulsation Analysis

Globular clusters have only little depth - we can treat all the stars in a cluster as being at \sim the same distance from Earth
color-magnitude diagram of stars in a globular cluster (M3):

all RR Lyrae stars have \sim the same apparent magnitude

\Rightarrow as the distance must be \sim the same, they also have the same absolute magnitude

once we know the value of that absolute magnitude, we can compute the distance to each star from the distance modulus

The Period-Luminosity(-Metallicity) Relation

A closer look:

for each RR Lyrae star in the cluster, plot the apparent magnitude as function of its period

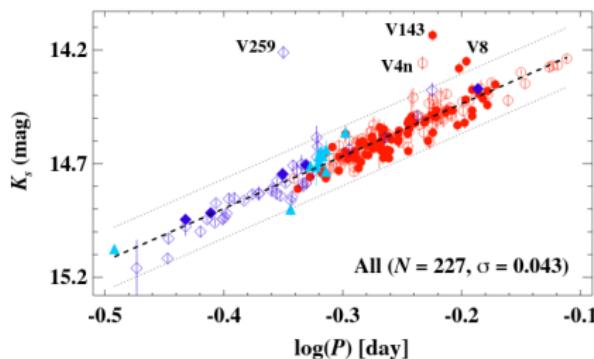

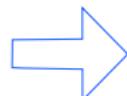

Figure 10 (slightly modified)
taken from Bhardwaj et al., AJ
160, 220 (2020)

slight **trend**: stars with longer periods are a bit brighter

The Period-Luminosity(-Metallicity) Relation

The Period-Luminosity(-Metallicity) Relation

To put everything together:

1. we know the **distance modulus** equation:

$$d = 10^{(m-M+5)/5} \text{ parsec}$$

2. stars at approximately the same distance show a slight **trend**: stars with longer periods are a bit brighter

- (3. There is also a small trend on metallicity Z .)

metallicity is the abundance of elements present in star that are heavier than hydrogen and helium

For $d(m, P, Z)$, we need to **calibrate** the Period-Luminosity(-Metallicity) Relation.

The Period-Luminosity(-Metallicity) Relation

calibrate the Period-Luminosity(-Metallicity) Relation:

The following methods can be used to determine absolute magnitudes, e.g.:

- Statistical study of the motions of field RR Lyrae stars: statistical parallax. This gives values of M_V ranging from +0.9 for short-period, high-metallicity stars, to +0.5 for longer-period, lower-metallicity stars. As a statistical method, it must be applied to a large sample of stars, which might not be homogeneous.

Q: What is the range of periods for these Cepheids?

A: The range is from $\log_{10}(P) = -0.1 \Rightarrow P = 0.8$ days to $\log_{10}(P) = +1.9 \Rightarrow P = 79$ days
 \Rightarrow that is about a factor of 100

The Period-Luminosity(-Metallicity) Relation

here we absolutely need a **period-luminosity relation**

The Period-Luminosity(-Metallicity) Relation

here we absolutely need a **period-luminosity relation**

to measure the distance to a Cepheid, we need to carry out four steps:

1. measure the average apparent magnitude m of the star
2. measure the period P of variation of brightness
3. use the period to compute the absolute magnitude M
4. use the distance-modulus formula to compute the distance to the star

The Period-Luminosity(-Metallicity) Relation

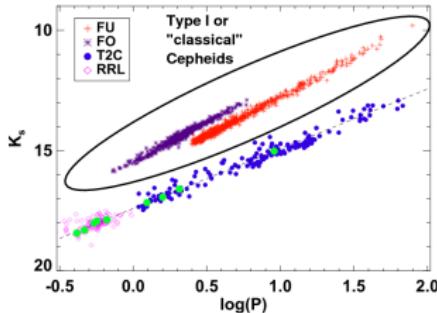

Figure 9. Comparison of K_s -band P-L relation with Classical Cepheids from LMCNISS data and RR Lyraes in the LMC. The green circles represent the calibrator T2Cs and RRLs.

Q: Write an equation of the form

$$M(V) = A \times \log_{10}(P) + B$$

which is consistent with the data in the graph.

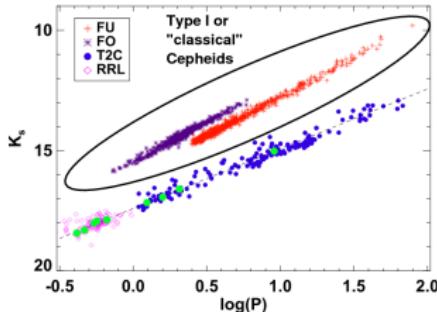

Figure 9. Comparison of K -band P-L relation with Classical Cepheids from LMCNISI data and RR Lyraes in the LMC. The green circles represent the calibrator T2Cs and RRLs.

Q: Write an equation of the form

$$M(V) = A \times \log_{10}(P) + B$$

which is consistent with the data in the graph.

A: From the line drawn on the diagram, we can find the endpoints $(0.6, -3.0)$ and $(2.0, -6.5)$. The slope of the line is then approximately

$$A = \frac{-6.5 - (-3.0)}{2.0 - 0.6} = -0.25$$

The Period-Luminosity(-Metallicity) Relation

example 3: A Period-Luminosity Relation for Cepheids

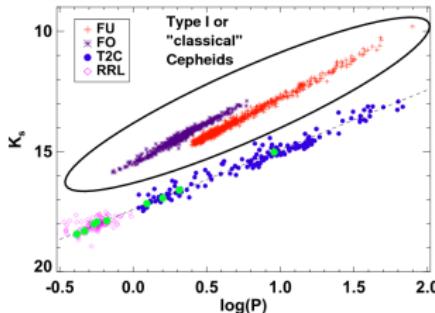

Figure 9. Comparison of K_s -band P-L relation with Classical Cepheids from LMCNISS data and RR Lyraes in the LMC. The green circles represent the calibrator T2Cs and RRLs.

Q: Write an equation of the form

$$M(V) = A \times \log_{10}(P) + B$$

which is consistent with the data in the graph.

A (continued): If we plug into the equation

$$-3.0 = (-2.5 \times 0.6) + B$$

and solve for B , we can find the y -intercept:

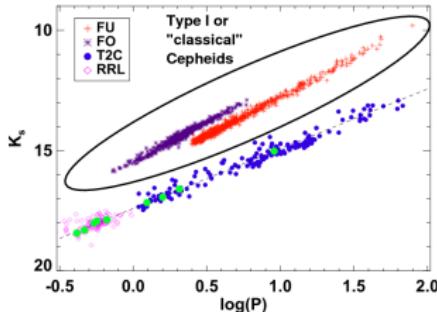

Figure 9. Comparison of K_s -band P-L relation with Classical Cepheids from LMCNIISS data and RR Lyraes in the LMC. The green circles represent the calibrator T2Cs and RRLs.

Q: Write an equation of the form

$$M(V) = A \times \log_{10}(P) + B$$

which is consistent with the data in the graph.

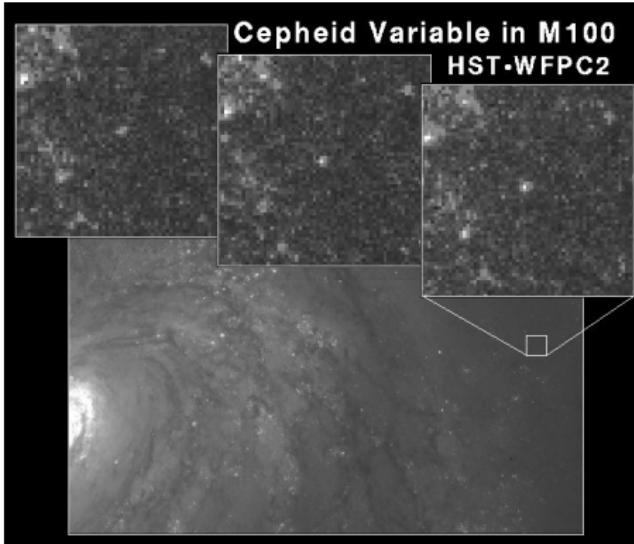

A (continued): So the relationship between period and absolute magnitude is approximately

$$M(V) = -2.5 \times \log_{10}(P) - 1.5$$

The Period-Luminosity(-Metallicity) Relation

example 4: The Distance to M100

We apply this relationship to measurements of Cepheid variable stars in a relatively nearby galaxy: M100.

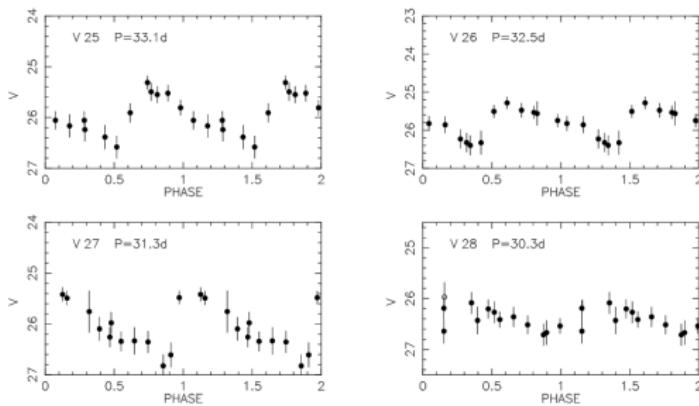

The Period-Luminosity(-Metallicity) Relation

Further Pulsation Analysis

example 4: The Distance to M100

We determine the period and apparent magnitude of a few Cepheid light curves in this galaxy.

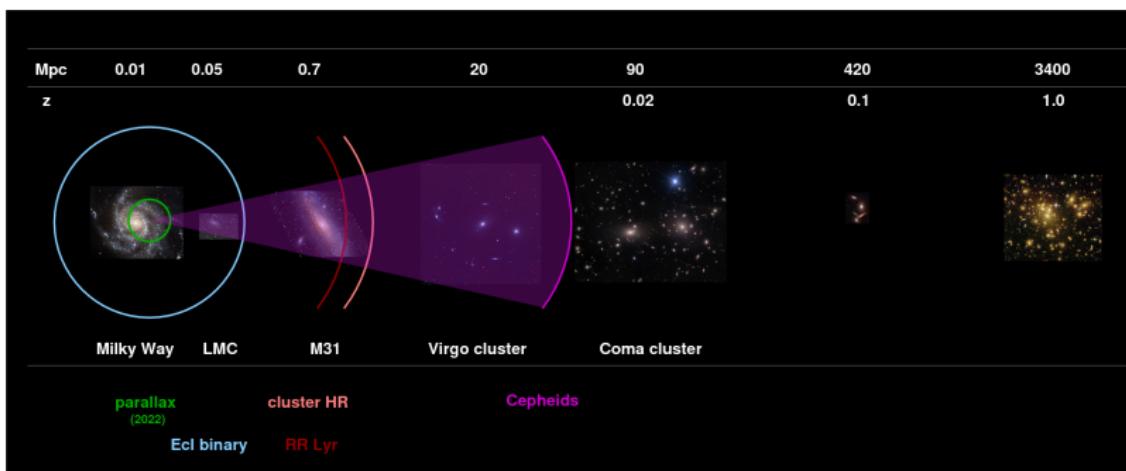

1. Pick one variable star. Measure its average apparent magnitude, m_V .
2. Use its period to determine its absolute magnitude M_V .
3. Compute the distance modulus ($m_V - M_V$).
4. Compute the distance to this galaxy, in Mpc.

Answer: You should get a distance of ~ 17 Mpc.

The Period-Luminosity(-Metallicity) Relation

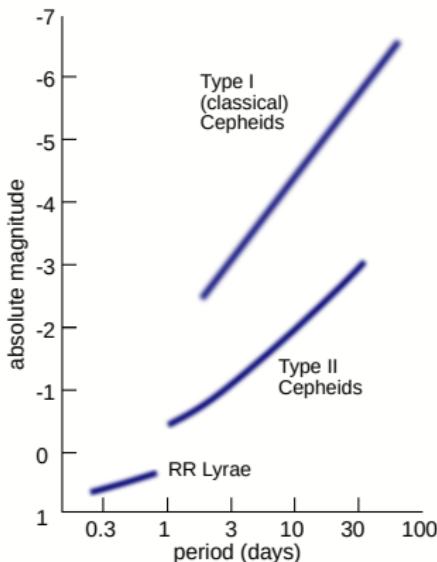

As Cepheids are more luminous than RR Lyrae, with them we can measure distances farther into the depths of space.

In particular, Cepheids allow to measure the distance to the nearest galaxy cluster, the Virgo Cluster.

Period-Luminosity(-Metallicity) Relations for Cepheids and RR Lyrae

Period-luminosity relations are known for several types of pulsating variable stars: type I Cepheids, type II Cepheids, RR Lyrae variables, Mira variables, and other long-period variable stars.

Period-Luminosity(-Metallicity) Relations for Cepheids and RR Lyrae

Population I Cepheids:

Population I Cepheids are stars with relatively high metallicity (like our Sun) and thus are *second generation* stars, found in the disk of our galaxy. Classical Cepheids (also known as Population I Cepheids, type I Cepheids, or Delta Cepheid variables) undergo pulsations with very regular periods on the order of days to months.

The following relationship between a Population I Cepheid's period P and its mean absolute magnitude M_v was established from Hubble Space Telescope trigonometric parallaxes for 10 nearby Cepheids (Thomas et al. (2007), Benedict et al. (2002)):

$$M_v = (-2.43 \pm 0.12)(\log_{10} P - 1) - (4.05 \pm 0.02)$$

Period-Luminosity(-Metallicity) Relations for Cepheids and RR Lyrae

Population II Cepheids:

Population II Cepheids are stars found in globular clusters that are low-metallicity "first generation" stars. Type II Cepheids are fainter than their classical Cepheid counterparts for a given period by about 1.6 magnitudes (about 4 times less luminous).

Period-Luminosity Relations of Population II Cepheids
(McNamara 1995):

$$P < 10 \text{ days: } M_v = -1.61 \log_{10} P - 0.05,$$

$$P > 10 \text{ days: } M_v = -4.17 \log_{10} P + 3.06$$

The steep slope for stars with $P > 10$ days may be due to an increase of mass with the period of pulsation.

Period-Luminosity(-Metallicity) Relations for Cepheids and RR Lyrae

RR Lyrae Stars:

The PLZ relation is given as (e.g. Catelan2004, Sollima2006):

$$M_\lambda = \alpha_\lambda \log_{10}(P/P_{\text{ref}}) + \beta_\lambda ([\text{Fe}/\text{H}] - [\text{Fe}/\text{H}]_{\text{ref}}) + M_{\text{ref},\lambda} + \epsilon$$

where λ denotes the bandpass, P is the period of pulsation, M_{ref} is the absolute magnitude at a reference period and metallicity, and α , β describe the dependence of the absolute magnitude on period and metallicity. The ϵ is a standard normal random variable centered on 0 and with a standard deviation of the uncertainty in M_λ in order to model the intrinsic scatter in the absolute magnitude convolved with unaccounted measurement uncertainties.

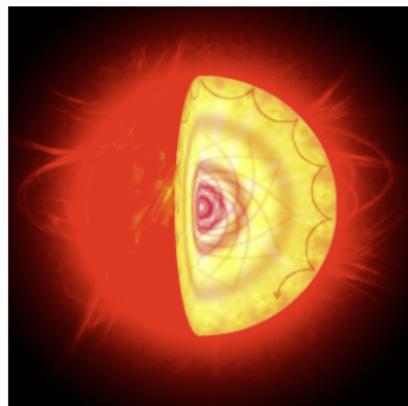

Further Pulsation Analysis

Motivation
Variable Stars
Pulsating Variable Stars
Distances
Further Pulsation Analysis

Pulsation is useful for **probing the interiors of stars**, and testing models of stellar structure and evolution:

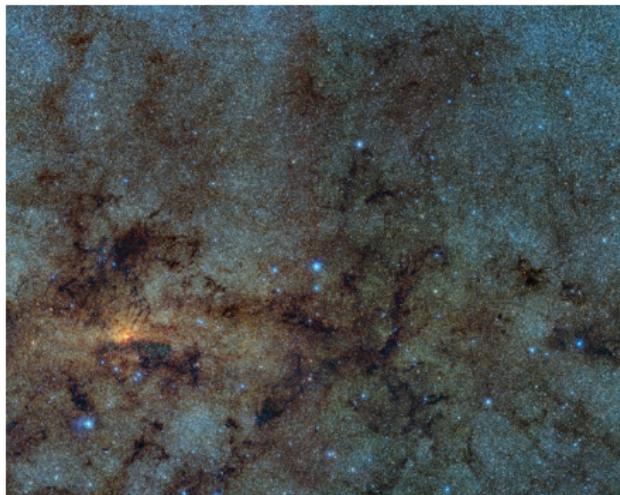

Asteroseismology.

Stars have many resonant modes and frequencies, and the path of sound waves passing through a star depends on the speed of sound, which in turn depends on local temperature and chemical composition.

Further Pulsation Analysis

As pulsating stars allow for calculating distances, we can use them to **estimate interstellar reddening** (from dust).

This IR view of the Milky Way's crowded center (taken as part of the ESO's VISTA Variables in the Via Lactea Survey) reveals numerous RR Lyrae stars in our galaxy's bulge, hinting that it is old and may have been built up as primordial star clusters merged over time.
